Dr. Monika

Department of Computer Science and Engineering,
Chitkara University, Punjab

- Economic development has traditionally been viewed as a process of **structural transformation**, where resources shift from agriculture to industry and services
- Classical theories considered **industrialization as the main driver of growth**, while agriculture was treated as a supporting or residual sector
- However, modern economic conditions have challenged this view due to:
 - Rising unemployment despite economic growth
 - Increasing income inequality
 - Environmental degradation and resource depletion
- Technological advancements and automation have reduced the **labour absorption capacity of industries**
- At the same time, sustainability concerns such as climate change and water scarcity are affecting long-term growth
- In this changing scenario, agriculture is being re-evaluated as a:
 - Source of employment
 - Driver of inclusive growth
- Key contributor to sustainable development

Objectives

- To examine the **traditional model of economic growth** based on structural transformation from agriculture to industry and services
- To analyze emerging challenges such as:
 - Jobless growth
 - Automation and capital-intensive production
 - Environmental sustainability issues
- To re-evaluate agriculture as an **active driver of growth**, rather than a passive sector
- To examine sectoral growth patterns and their impact on:
 - Employment generation
 - Income distribution
 - Economic inclusiveness
- To assess the effectiveness of **agriculture-led growth strategies**
- To develop a **new growth model** that integrates sustainability and inclusiveness
- To identify policy directions for balanced and long-term development

- Existing models assume a **linear transition** from agriculture → industry → services, which does not reflect real-world complexity
- Limited research on **agriculture as a central growth driver** in modern economies
- Lack of studies connecting:
 - Growth patterns with employment generation
 - Sectoral growth with labour absorption
- Insufficient integration of **environmental sustainability** into economic development models
- Minimal focus on agriculture's dual role:
 - Resource-intensive sector
 - Sustainability solution
- Limited state-level and regional comparative studies (especially in India)
- Existing studies analyze sectors separately rather than as an **interconnected system**

Key Challenges

- Rising **jobless growth**, where output increases but employment does not
- Increasing use of **automation and capital-intensive technologies**, reducing labour demand
- Weak labour absorption in both:
 - Industrial sector
 - Service sector
- Structural imbalance:
 - Labour leaving agriculture faster than other sectors can absorb
- Growth of informal and underemployment
- Rising **income inequality** between rural and urban areas
- Regional disparities across states in development patterns
- Unsustainable use of resources such as groundwater and fertilizers
- Lack of coordination between agriculture, industry, and services
- Incomplete and uneven structural transformation

- Study adopts a **descriptive and analytical research design**
- Focuses on understanding economic growth patterns and sectoral dynamics
- Based entirely on **secondary data sources** such as:
 - Research papers and academic journals
 - Government reports and economic surveys
 - Census and statistical databases
- **Scope of Study**
- Primarily focused on **India**, with global references
- Sectoral analysis of growth patterns
- Comparative analysis across Indian states
- Trend analysis of employment and productivity
- Conceptual analysis of development theories
- **Techniques Used**
- Qualitative analysis and interpretation
- Logical reasoning and comparative evaluation

- Data Sources & Tools:
- Academic journals and research publications
- Government databases (Economic Survey, Census data)
- International reports (OECD, development organizations)
- Analytical Tools:
- Comparative analysis techniques
- Trend analysis of sectoral growth
- Conceptual frameworks for economic development
- Statistical summaries and data interpretation
- Visualization Tools:
- Tables for sector comparison
- Graphs showing employment trends
- Conceptual diagrams (growth models)

- Agriculture remains a **key driver of economic growth**, especially in early development stages
- Agricultural growth:
 - Reduces poverty
 - Generates employment
 - Increases rural income
- Strong **linkages** observed:
 - Backward linkages (inputs like machinery, fertilizer)
 - Forward linkages (processing, services)
- Industry and services contribute to GDP but generate limited employment
- Labour shift from agriculture not properly absorbed → unemployment
- **Income Inequality**

Thank You
